Lesson 9-2 The Reciprocal Function Family

We all know what the reciprocal of a number is: one over the number, the reciprocal of a is $\frac{1}{a}$, the reciprocal of 5 is $\frac{1}{5}$. Well, functions like inverse variations, are in a reciprocal form, hence we call these functions reciprocal functions. Generally speaking we will see the x variable in the denominator: $f(x) = \frac{1}{x}$. Of course reciprocal functions can and will be more complicated so we need to be familiar with the complete form of a reciprocal function which is: $y = \frac{a}{x-h} + k$ (note the restriction on the domain of $x \neq h$). Here again are h and k which translate the parent function.

Graphing

- Graph $y = \frac{8}{x}$ and identify vertical and horizontal asymptotes. 1. Make a table of values that include both positive and negative values
 - 2. Graph the points and draw a line
 - 3. Asymptotes will be at domain restrictions, that is where x cannot be equal to zero is a vertical asymptote. No matter how big or small x becomes, y will never be equal to zero, hence, the horizontal asymptote.

Asymptotes at x=0 and y=0

Asymptotes

Often we can see on the graph what the asymptotes are, but how can we look at the equation and determine the asymptotes? Let's take a look at that general form of a reciprocal function; the "h and k" are significant: $y = \frac{a}{x-h} + k$ The denominator cannot be equal to zero, so set it to zero and solve for x. At x = h we have a vertical asymptote and at y = k we have a horizontal asymptote. So by putting the function into our general form, we can pluck off the asymptotes.

Also, if given a parent reciprocal function and asymptotes, we can develop an equation with the given asymptotes that will be a translation of the parent function.

Identify the asymptotes for:

 $y = -\frac{2}{x} - 3$ $y = -\frac{2}{x-0} - 3$ h = 0 and k = -3

vertical asymptote: x = 0horizontal asymptote y = -3

Now try and sketch:

$$y = -\frac{10}{x+1} - 8$$

- 1. write in general form:
- 2. identify values for **h** and **k**
- 3. label as asymptotes.
- 1. identify **h** and **k**

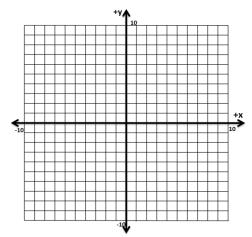

2. put reciprocal function **h** and **k** into the general equation

For the reciprocal function of $\frac{2}{x}$ write the translation given asymptotes of

x = -2 and y = 3h = -2 and k = 3

$$y = \frac{2}{x - (-2)} + 3 \therefore y = \frac{2}{x + 2} + 3$$

Graph:

Note: on the graph how the curves shift 2 units to the left and 3 units up

Now try:

Graph the functions and find the approximate point (s) of intersection: $y = \frac{3}{x+1}$, y = -4
